

Figure 2.27. Blocky mudstone in the middle Farley as it appears on weathered outcrop. Note the blocky texture and color variations. (locality MCI)

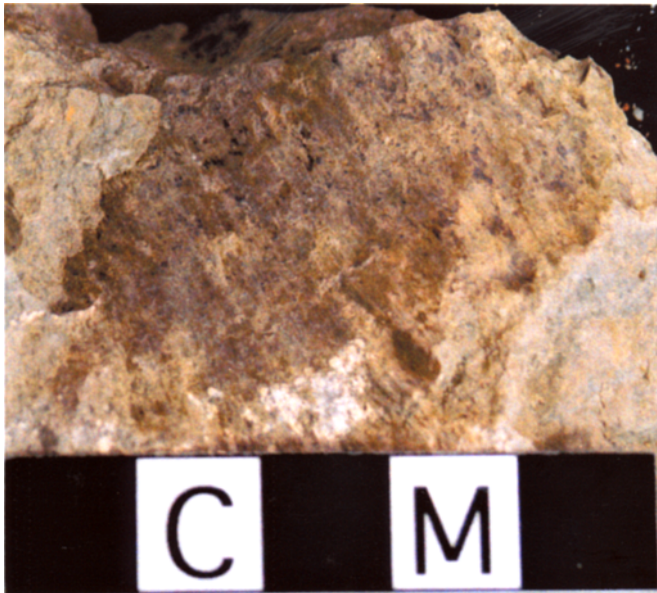

Figure 2.28. Detail photograph of ped surface from the blocky mudstone facies. Note the glossy appearance and the striations on the surface. The glossy coating is the soil cutan and the striations are soil slickensides (sample from middle Farley, locality SRS).

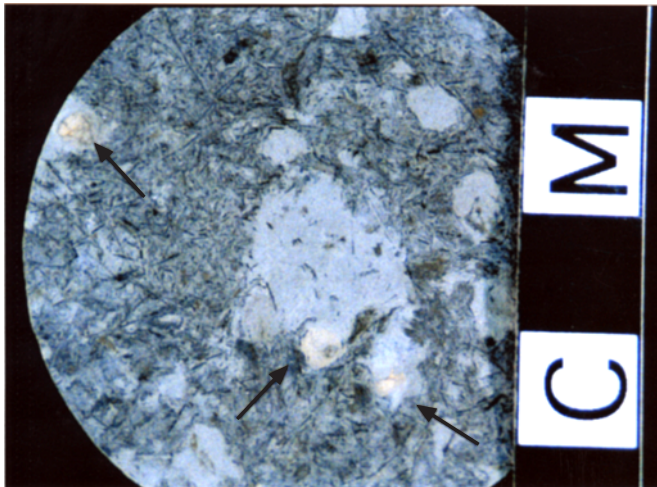

Figure 2.29. Cross-section of core section with abundant plant material. Plant material (leaf, root and twig fragments) is very abundant in the blocky mudstone facies and is typically well preserved. Also note vertical root tubes visible in the core (arrows) (Core #4-Island Creek).
